

Solaris

RenderMan for Houdini needs to be installed for full functionality of RenderMan in Solaris.

RenderMan supports the native USD "Solaris" workflows introduced in Houdini 18. Solaris offers artists and TDs:

- Access to native USD for scene composition, variants, and overrides. USD is a robust technology for building up assets, putting them into sets, and adding shot specific details and animation. It is a great pipeline tool.
- A new lighting toolset that allows artists to build lights into their USD scenes.
- Direct batch rendering of USD files via Houdini's "husk" command-line renderer.

RenderMan provides a USD Hydra Renderer Delegate that allows artists to render interactively directly to the Solaris viewport. Artists get immediate path-traced visual feedback during scene assembly, adjustments to lighting, materials, and other scene attributes. The same RenderMan Hydra Renderer Delegate is what also allows the "husk" command-line renderer.

As the SideFX builds on Solaris, RenderMan will continue to provide deep matching integrations to new features and capabilities.

For more information, please consult the other sections of our documentation, as well as from the USD documentation and the Solaris documentation:
