

RenderMan 26 for Katana

Katana's powerful and flexible look development environment combined with RenderMan's state-of-the-art rendering technology come together to offer the user a remarkable out-of-the-box experience for high-end lighting and rendering.

RenderMan for Katana (RfK) provides seamless access to RenderMan's powerful rendering system for Katana users, who can take advantage of the plugin's flexibility to create an optimal, customized pipeline.

Installation

RenderMan for Katana requires the installation of the RenderMan Pro Server as well as the RfK plugin in order to function correctly. The RenderMan installer does this automatically.

About the Plugin

The RenderMan plugin for Katana plays a dual role in a production pipeline; it is the bridge by which a user generates rendered images from a Katana scene as well as the provider of access to the tools for building the 3D elements within the scene.

Although RfK is generally referred to as a "plugin" it is in actuality a collection of plugins, nodes, macros, and other tools which together allow the Katana user full access to the PRMan rendering system.

Included in the RfK plugin package:

- Rendering plugin
- Renderer introspection plugin
- Device drivers for interactive renders
- GafferThree extensions for PRMan lights
- Viewer plugins and manipulators for PRMan lights
- Macros for features such as Denoise and Holdouts
- Nodes for PRMan render configuration
- Tutorial scenes

There is no need to "load" the RfK plugin. Once it is [installed](#) and [configured](#) Katana will find the package automatically and load the various modules as needed.

Live Rendering

Vastly improved Live Rendering is iterative rendering where you can change parts of your scene and see it update in the render. Live rendering improves lighting and shading iteration. RfK supports offers the following features:

- Edits to material parameters, adding/deleting, and editing of shading nodes

- Edits to attributes and transform of lights and light filters, including mesh lights.
- Edits to shapes and transforms for objects
- Import and Export assets while Live Rendering
- Object picking in the Monitor with the pixel probe.
- Addition of lights (analytic and mesh) and object creation during live rendering.
- Live updates of renderSettings (ROI, cropWindow, resolution)
- Live updates of integrators and options (as supported by PRMan)
- Live authoring of AOVs

Lighting and Shading

RenderMan ships with built-in production-quality shaders and lights, the same [shaders](#) and [lights](#) in use by Pixar Animation Studios on their feature films. Pixar shaders are loaded automatically at startup and available through the standard Katana material workflows. Pixar lights can be created in GafferThree with a [single key-stroke](#) or directly via the menu. Mesh lights can also be created by simply selecting the geometry and creating a PxrMeshLight. Viewer Plugins and Manipulators are also included for the built-in lights and light filters.

For more information, see the following documentation:

- [Shading in Katana](#)
- [Lighting in Katana](#)

Plugin Customization

RenderMan For Katana supports studio customization via custom Ops.

Image Tool (it)

RenderMan includes "[it](#)", a robust framebuffer/render view window that offers complete floating point support and a powerful and flexible catalog. "it" is a fast and powerful imaging tool that is capable of production-quality image manipulation and compositing usually found only in high-end standalone products. Thanks to its integration with the plugin and an all-new Python scripting interface, "it" gives users the ability to incorporate sophisticated post-render image operations into their rendering pipeline.

RenderMan Features

Photo Realistic RenderMan (PRMan) is designed to be fast and easy to use while generating production-quality renders and global illumination works out of the box and live rendering provides rapid iteration for artists. RenderMan for Katana supports all aspects of PRMan through both standard and PRMan-specific nodes.

Interactive Rendering

RenderMan supports updating a scene during rendering. Many features are supported including importing and exporting assets on-the-fly, animation, transformation, light and material parameter changes and more!

Fast Ray Tracing Core

To complement the improvements to interactive rendering are improvements to the ray tracing core of RenderMan. Speed and quality are improved to provide a fast and seamless experience while the artist works.

Immediate Rendering

Stop waiting for a render to begin. RenderMan skips the RIB generation process when rendering in interactive sessions to give users control and results as quickly as possible.

Analytic Area Lights

Area Lights are a powerful way to create physically accurate lighting while optimizing sampling budgets and, in turn, performance. PRMan's [area lights](#) support light [filters](#), as well as light-linking, groups, per-group AOVs, and IES profiles and portals.

Global Illumination

Sometimes called "Indirect Illumination," RenderMan for Katana supports Global Illumination effects, subtle diffuse shading effects that are created by sampling the lighting of a scene many times from a given point. This technique can yield highly realistic results. Occlusion, which merely samples the "coverage" of a point (and is cheaper than Indirect Illumination), is also supported automatically or through the [PxrOcclusion](#) Integrator.

Volume Rendering

RfK supports PRMan's first-class [volumetric](#) rendering capabilities, enabling the creation of volumetric effects including motion blur, multi-scattering, non-homogenous, etc.

True Curved Surfaces

Tessellation settings are never an issue with RenderMan when rendering [NURBS](#) and [subdivision](#) surfaces. Since RenderMan renders true curved surfaces, NURBS and subdivision surfaces will never have faceting artifacts.

Subsurface Scattering

RenderMan for Katana supports path-traced subsurface scattering, an important effect for realistically rendering translucent materials, like skin, flesh, fat, fruits, milk, marble, and many others. Subsurface scattering is responsible for effects like color bleeding inside materials, or the diffusion of light across shadow boundaries. RfK includes support for ray-traced subsurface scattering through materials shipped with RenderMan.

Secondary Outputs

RenderMan for Katana supports secondary outputs (AOVs, or Arbitrary Output Variables), which can be any arbitrary information contained in a shader. Users may also take advantage of [Light Path Expressions](#) (LPE) for powerful control over outputs.

Down the Pipe(line)

RenderMan for Katana is one piece of a potentially sophisticated production pipeline. In order to get your work from script-to-screen you may need more, and that is where Tractor enters the picture. By implementing RfK in concert with Tractor and RenderMan Pro Server users can achieve a seamlessly integrated rendering workflow from desktop to renderfarm.

Tractor

[Tractor](#) is a system for distributing tasks from queued jobs to a farm of execution servers, managing large queues of concurrent jobs from many users, enforcing dependencies and scheduling policies. The Tractor package includes a central queueing mechanism, a remote execution server, a monitoring subsystem, and a browser-based user interface.

Tractor is provided as a separate, standalone product, with its own documentation.

RenderMan Pro Server

RenderMan Pro Server is the foundation of a high-performance rendering pipeline. It provides standalone implementations of the renderer and its corresponding rendering utilities as well as access to APIs that allow savvy users to extend functionality. As the core technology, RenderMan Pro Server is the font from which all pixels flow.
